INTRODUCTION

The Fifteenth Bulletin of North Carolina morbidity statistics, covering the calendar year 1946, contains tabulations of the thirty-five communicable diseases reportable in this state since 1944.

In this report there are only two diseases that appear to have a definite upward trend over a ten-year period. These are gonorrhea and Rocky Mountain spotted fever. The increase in gonorrhea may be due, wholly or in part, to an improvement in reporting. Insufficient evidence is available at present to decide this question. The Rocky Mountain spotted fever rate of 1.7 cases per 100,000 population, although the highest in the past ten years, does not represent a great increase over the previous highs of 1.5 in 1944 and 1.2 in 1938. This disease will bear watching, however.

Encouraging declines have taken place in diphtheria, typhoid fever, and whooping cough in the past ten years. The 1946 rates for diphtheria and typhoid fever are the lowest on record. The 1946 rate for whooping cough is the lowest ever recorded except for the year 1936.

Malaria, which was prevalent to a limited extent in returning service men, apparently has not increased in incidence in the civilian population. Endemic typhus fever, which increased over a period of ten years to set a new high in 1944, has now declined for two years in succession. Two smallpox cases occurred in 1946. The first year of no reports of this disease is still to come.

Reports of primary and secondary cases of syphilis rose sharply this year. This increase is probably associated with the return of service men. Although reports of late cases continued to decline, the rise in early cases was large enough to cause an increase in the total for all stages combined, for the first time since 1939.

Tuberculosis cases were more numerous in 1946 than in the previous year; however, the fact that tuberculosis deaths set a record low this same year shows that improved case-finding is responsible for the rise in mortality. More tuberculosis cases are being located early, as is shown by the fact that 53.3 per cent of the active cases reported in 1946 were minimal or only moderately advanced while 51.7 per cent of the 1945 cases were in these stages.

Tularemia cases in 1946 were double those for 1945, which were also decidedly increased over the previous year. During the ten years previous to 1945 the tularemia morbidity rate remained relatively constant. The increases of the past two years may be significant in view of this fact.

Undulant fever declined somewhat this year to offset the slight increase that occurred in 1944.

Changes in the morbidity rates of the other reportable diseases are not of particular significance.

INTRODUCTION

The Fifteenth Bulletin of North Carolina morbidity statistics, covering the calendar year 1946, contains tabulations of the thirty-five communicable diseases reportable in this state since 1944.

In this report there are only two diseases that appear to have a definite upward trend over a ten-year period. These are <u>pneumonia</u> and <u>Rocky Mountain spotted fever</u>. The increase in pneumonia may be due, wholly or in part, to an improvement in reporting. Insufficient evidence is available at present to decide this question. The Rocky Mountain spotted fever rate of 1.7 cases per 100,000 population, although the highest in the past ten years, does not represent a great increase over the previous highs of 1.5 in 1944 and 1.2 in 1938. This disease will bear watching, however.

Encouraging declines have taken place in <u>diphtheria</u>, <u>typhoid fever</u>, and <u>whooping cough</u> in the past ten years. The 1946 rates for diphtheria and typhoid fever are the lowest on record. The 1946 rate for whooping cough is the lowest ever recorded except for the year 1936.

<u>Malaria</u>, which was prevalent to a limited extent in returning service men, apparently has not increased in incidence in the civilian population. <u>Endemic typhus fever</u>, which increased over a period of ten years to set a new high in 1944, has now declined for two years in succession. Two <u>smallpox</u> cases occurred in 1946. The first year of no reports of this disease is still to come.

Reports of primary and secondary cases of <u>syphilis</u> rose sharply this year. This increase is probably associated with the return of service men. Although reports of late cases continued to decline, the rise in early cases was large enough to cause an increase in the total for all stages combined, for the first time since 1939.

<u>Tuberculosis</u> cases were more numerous in 1946 than in the previous year; however, the fact that tuberculosis deaths set a record low this same year shows that improved case-finding is responsible for the rise in morbidity. More tuberculosis cases are being located early, as is shown by the fact that 53.3 per cent of the active cases reported in 1946 were minimal or only moderately advanced while 51.7 per cent of the 1945 cases were in these stages.

<u>Tularemia</u> cases in 1946 were double those for 1945, which were also decidedly increased over the previous year. During the ten years previous to 1945 the tularemia morbidity rate remained relatively constant. The increase of the past two years may be significant in view of this fact.

<u>Undulant fever</u> declined somewhat this year to offset the slight increase that occurred in 1944.

Changes in the morbidity rates of the other reportable diseases are not of particular significance.
